

Wait, that seems quite high. Maybe I made a mistake. **Let me check** my calculations again.

Then, another 20 marbles are pulled out, and 1 was black. **Wait**, let's analyze this carefully

Wait, no, that might not be the right way. Let me reframe it.

0-20% states

Wait, the order might matter. So it's $5 + (19? - 17)$. Let me ensure I'm calculating correctly.

Wait a minute, that's interesting because $P(A)$ is already 0.2, so in this case, $P(A|B) = P(A)$. Does that make sense?

But wait, the problem just asks to find the multiple of X , not provided specifically, that is divisible by both 9 and 12. Hmm, that seems a bit generic. Maybe I misread. **Let me check again**.

Let me check the setup. After the second pull, the bag has $N + 40$ marbles, with 20 black marbles. The percentage of black marbles is $20/(N + 40) = 5\% = 0.05$.

Perhaps I **made a mistake** in setting up the equation. Let's check.

Wait, but let me double-check my calculations to make sure I didn't make a mistake.

20-40% states

Wait, so walking more steps and stopping takes longer?

Wait, but I should double-check to make sure I didn't make any mistakes in my calculations. Alternatively, maybe I can think about it another way.

But wait, the letters in 'PROBLEC' each have different frequencies. **Let me check that**.

Still not matching the options. The closest option is 226 and 230. Did I make a mistake in calculation? **Let me check**.

But perhaps I **made a mistake** in my reasoning. Let me double-check.

Wait, maybe I'm overcomplicating. Let's think about it differently.

40-60% states

Wait, that can't be right because probabilities can't exceed 1.

Wait, in the first case, the elevator covers 20 steps in 10 minutes, so speed = $20 / 10 = 2$ steps per minute.

But none of the answer choices are given in this decimal form. **Let me check** the answer options again

Maybe the problem is designed to have one of the options, but I must have miscalculated. **Let me check the math once more**.

Wait, that's incorrect. It should be $(5 + 19? - 15 - 7)/13 = 6$, which simplifies to $(19? - 17)/13 = 6$

Wait, perhaps using the sine of the angles would be more straightforward.

60-80% states

Wait, probabilities cannot be negative. There must be an error in this approach. Let me reconsider.

Wait, let's go back. The equation after removing 0.5P was ...

So, $21.90 / 0.28 = 77.50$, but **let me check** that again because my initial division seems not to align with this.

Wait, perhaps I read the problem wrong. **Let me check again**.

Wait, maybe it's better to calculate step by step.

Wait, I think I need to reconsider my approach. Let me try again.

80-100% states

Wait, but the problem says that they reach in 10 minutes. So perhaps only T1 plus T2 equals 10.

So, unless I **made a mistake** in setting up the equation, which doesn't seem so, the answer should be 4,000, which is option A.

Wait, unless the 2% is on the defective Staplers? **Let me check** the problem again

● thought ● let me check ● wait ● make a mistake
