

Since probabilities can't exceed 1, the maximum value of $P(A \text{ and } B)$ can be the minimum of $P(A)$ and $P(B)$. The minimum of 0.56 and 0.74 is 0.56. Wait, maybe. **Let me check again.**

Wait, this might be a bit more complicated. Let's try to think of it in terms of relative motion.

Wait, actually when solving $D = \frac{1}{2}at^2(D - 10v)$, let's do it again step by step.

0-20% states

But maybe it's a trick question where the letters have to be distinct? **Wait**, the first part might assume whether letters can repeat or not,

Wait, first maybe I need to find the total distance.

Let me check that again. Yes: the non-defective total is $0.9N$, and 2% of that is rejected. Therefore, $0.02 \cdot (0.9N) = 72$.

...plus 54,400 gives 1,180,800? **Wait, let me check again.** $626,400 + 554,400 \dots$

Wait, but perhaps I missed something.

Wait, in the previous step, the time remaining is (d/v) . So after substitution,...

20-40% states

Wait a second. But hold on, let me double-check because maybe I'm oversimplifying.

But **wait**, looking at the answer options, E is 110. However, the problem says "at least" so maybe there's a catch here?

Wait, but maybe I made an arithmetic mistake somewhere. **Let me check the division again:**

Wait, but this calculation gives exactly $5(\frac{1}{2}at^3 + 1)$, which is option A. But wait, **let me check** once more.

Wait, perhaps subtract equation 1 multiplied by some factor.

Hmm, that discrepancy is odd. Maybe I **made a mistake** in the equation setup?

40-60% states

Wait, wait. Wait a second, no, actually, maybe I made a calculation error here. Let me double-check because that result seems a bit low. Let me recalculate the division:

Wait, let me redo the division.

Wait, perhaps my total cost calculation was wrong. **Let me check again.**

Let me check the options again. The problem's options are A)27, B)81, C)90, D)99, E)110. So according to this, the answer should be E. But the question might be a trick here?

Wait, sorry, let me recast...

...**Wait**, but maybe there is another approach?

60-80% states

$(N - 10 - 20e) = (N - 20 - 10e)/2 \cdot 2$? **Wait**, no. **Wait**, perhaps better to substitute.

Wait, but the options include C as 36. So that works. Let me confirm again step by step. Let me see:

Wait but let me think again. Maybe the question is asking for the number of staplers produced that day, which is the total N , so yes. The steps seem correct. **Let me check** with another approach.

...perhaps the original price was a value that when discounted and subtracted by 20 gives exactly the value needed. **Let me check.**

That's not among the options provided. Did I **make a mistake** somewhere?

Wait, maybe I confused steps here. Let me re-express

80-100% states

Wait, let me double-check my calculation step again. Maybe my math was wrong.

Let me do the calculation in decimals without converting to fractions. Maybe I **made a mistake** there.

But wait the options are A)4 B)4.5 C)5 D)5.5 E)6.5. So yes, C is correct. **Let me check** if there was any miscalculation. Hmm, yes, all steps check out.

● thought ● let me check ● wait ● make a mistake
